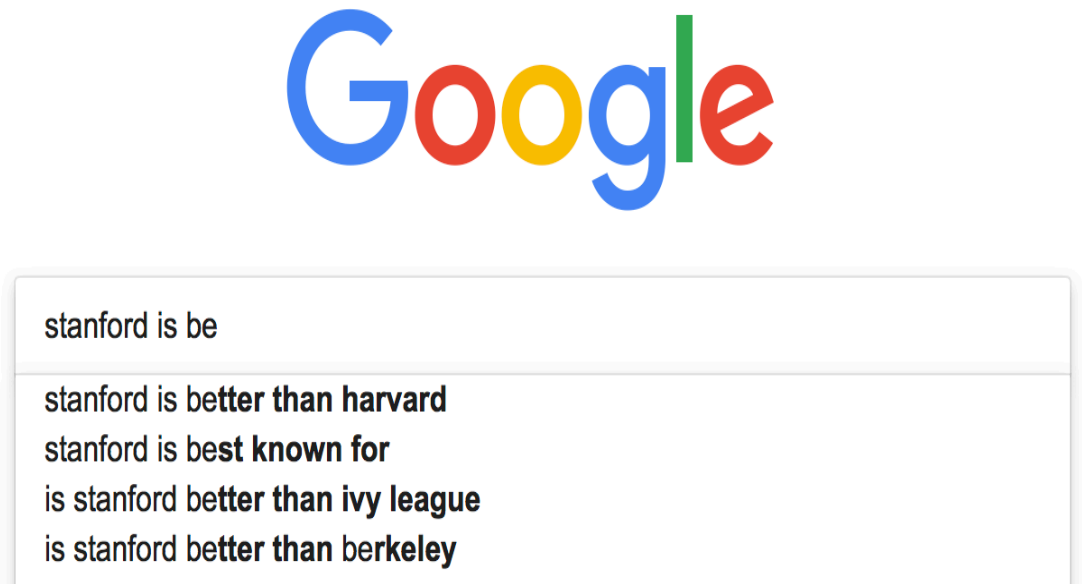
Assignment 3: Language Models: Auto-Complete

In this assignment, you will build an auto-complete system. Auto-complete system is something you may see every day

- When you google something, you often have suggestions to help you complete your search.
- When you are writing an email, you get suggestions telling you possible endings to your sentence.

By the end of this assignment, you will develop a prototype of such a system.



Important Note on Submission to the AutoGrader

Before submitting your assignment to the AutoGrader, please make sure you are not doing the following:

1. You have not added any *extra* `print` statement(s) in the assignment.
2. You have not added any *extra* code cell(s) in the assignment.
3. You have not changed any of the function parameters.
4. You are not using any global variables inside your graded exercises. Unless specifically instructed to do so, please refrain from it and use the local variables instead.
5. You are not changing the assignment code where it is not required, like creating *extra* variables.

If you do any of the following, you will get something like, `Grader Error: Grader feedback not found` (or similarly unexpected) error upon submitting your assignment. Before asking for help/debugging the errors in your assignment, check for these first. If this is the case, and you don't remember the changes you have made, you can get a fresh copy of the assignment by following these [instructions (https://www.coursera.org/learn/probabilistic-models-in-nlp/supplement/saGQf/how-to-refresh-your-workspace)](https://www.coursera.org/learn/probabilistic-models-in-nlp/supplement/saGQf/how-to-refresh-your-workspace).

- 3 - Perplexity
  - Exercise 10 - calculate_perplexity (UNQ_C10)
- 4 - Build an Auto-complete System
  - Exercise 11 - suggest_a_word (UNQ_C11)

A key building block for an auto-complete system is a language model. A language model assigns the probability to a sequence of words, in a way that more "likely" sequences receive higher scores. For example,

> "I have a pen" is expected to have a higher probability than "I am a pen" since the first one seems to be a more natural sentence in the real world.

You can take advantage of this probability calculation to develop an auto-complete system. Suppose the user typed

> "I eat scrambled" Then you can find a word x such that "I eat scrambled x" receives the highest probability. If x = "eggs", the sentence would be "I eat scrambled eggs"

While a variety of language models have been developed, this assignment uses **N-grams**, a simple but powerful method for language modeling.

- N-grams are also used in machine translation and speech recognition.

Here are the steps of this assignment:

1. Load and preprocess data
   - Load and tokenize data.
   - Split the sentences into train and test sets.
   - Replace words with a low frequency by an unknown marker `<unk>`.
2. Develop N-gram based language models
   - Compute the count of n-grams from a given data set.
   - Estimate the conditional probability of a next word with k-smoothing.
3. Evaluate the N-gram models by computing the perplexity score.

1 - Load and Preprocess Data

1.1 - Load the Data

You will use twitter data. Load the data and view the first few sentences by running the next cell.

Notice that data is a long string that contains many many tweets. Observe that there is a line break "\n" between tweets.

In [2]:
```
with open("./data/en_US.twitter.txt", "r") as f:
    data = f.read()
print("Data type:", type(data))
print("Number of letters:", len(data))
print("First 300 letters of the data")
print("-------")
display(data[0:300])
print("-------")

print("Last 300 letters of the data")
print("-------")
display(data[-300:])
print("-------")
```

```
Data type: <class 'str'>
Number of letters: 3335477
First 300 letters of the data
-------

"How are you? Btw thanks for the RT. You gonna be in DC anytime soon? Love t
o see you. Been way, way too long.\nWhen you meet someone special... you'll
know. Your heart will beat more rapidly and you'll smile for no reason.\nthe
y've decided its more fun if I don't.\nSo Tired D; Played Lazer Tag & Ran A
"

-------
Last 300 letters of the data
-------

"ust had one a few weeks back....hopefully we will be back soon! wish you th
e best yo\nColombia is with an 'o'...“: We now ship to 4 countries in South
America (fist pump). Please welcome Columbia to the Stunner Family”\n#Gutsie
stMovesYouCanMake Giving a cat a bath.\nCoffee after 5 was a TERRIBLE ide
a.\n"

-------
```

1.2 - Pre-process the Data

Preprocess this data with the following steps:

1. Split data into sentences using "\n" as the delimiter.
2. Split each sentence into tokens. Note that in this assignment we use "token" and "words" interchangeably.
3. Assign sentences into train or test sets.
4. Find tokens that appear at least N times in the training data.
5. Replace tokens that appear less than N times by `<unk>`

Note: we omit validation data in this exercise.

- In real applications, we should hold a part of data as a validation set and use it to tune our training.
- We skip this process for simplicity.

Exercise 1- split_to_sentences

Hints

In [3]:
```
# UNQ_C1 (UNIQUE CELL IDENTIFIER, DO NOT EDIT)
### GRADED_FUNCTION: split_to_sentences ###
def split_to_sentences(data):
    """
    Split data by linebreak "\n"

    Args:
        data: str

    Returns:
        A list of sentences
    """
    ### START CODE HERE (Replace instances of 'None' with your code) ###
    sentences = data.split('\n')
    ### END CODE HERE ###

    # Additional clearning (This part is already implemented)
    # - Remove leading and trailing spaces from each sentence
    # - Drop sentences if they are empty strings.
    sentences = [s.strip() for s in sentences]
    sentences = [s for s in sentences if len(s) > 0]

    return sentences
```

In [4]:
```
# test your code
x = """
I have a pen.\nI have an apple. \nAh\nApple pen.\n
"""
print(x)

split_to_sentences(x)
```

```
I have a pen.
I have an apple.
Ah
Apple pen.
```

Out[4]:
```
['I have a pen.', 'I have an apple.', 'Ah', 'Apple pen.']
```

Expected answer:

```
['I have a pen.', 'I have an apple.', 'Ah', 'Apple pen.']
```

In [5]:
```
# Test your function
w3_unittest.test_split_to_sentences(split_to_sentences)
```

```
 All tests passed
```

Processing math: 100%

Exercise 2 - tokenize_sentences

The next step is to tokenize sentences (split a sentence into a list of words).

- Convert all tokens into lower case so that words which are capitalized (for example, at the start of a sentence) in the original text are treated the same as the lowercase versions of the words.
- Append each tokenized list of words into a list of tokenized sentences.

Hints

In [6]:

```
import re

# UNQ_C2 (UNIQUE CELL IDENTIFIER, DO NOT EDIT)
### GRADED_FUNCTION: tokenize_sentences ###
def tokenize_sentences(sentences):
    """
    Tokenize sentences into tokens (words)

    Args:
        sentences: List of strings

    Returns:
        List of lists of tokens
    """

    # Initialize the list of lists of tokenized sentences
    tokenized_sentences = []
    ### START CODE HERE (Replace instances of 'None' with your code) ###

    # Go through each sentence
    for sentence in sentences:

        # Convert to lowercase letters
        sentence = sentence.lower()

        # Convert into a list of words
        tokenized = nltk.word_tokenize(sentence)

        # append the list of words to the list of lists
        tokenized_sentences.append(tokenized)

    ### END CODE HERE ###

    return tokenized_sentences
```

In [7]:

```
# test your code
sentences = ["Sky is blue.", "Leaves are green.", "Roses are red."]
tokenize_sentences(sentences)
```

Out[7]:

```
[['sky', 'is', 'blue', '.'],
 ['leaves', 'are', 'green', '.'],
 ['roses', 'are', 'red', '.']]
```

Expected output

```
[['sky', 'is', 'blue', '.'],
 ['leaves', 'are', 'green', '.'],
 ['roses', 'are', 'red', '.']]
```

In [8]:
```
# Test your function
w3_unittest.test_tokenize_sentences(tokenize_sentences)
```

```
All tests passed
```

Exercise 3 - get_tokenized_data

Use the two functions that you have just implemented to get the tokenized data.

- split the data into sentences
- tokenize those sentences

In [10]:
```
# UNQ_C3 (UNIQUE CELL IDENTIFIER, DO NOT EDIT)
### GRADED_FUNCTION: get_tokenized_data ###
def get_tokenized_data(data):
    """
    Make a list of tokenized sentences

    Args:
        data: String

    Returns:
        List of lists of tokens
    """
    ### START CODE HERE (Replace instances of 'None' with your code) ###

    # Get the sentences by splitting up the data
    sentences = split_to_sentences(data)

    # Get the list of lists of tokens by tokenizing the sentences
    tokenized_sentences = tokenize_sentences(sentences)

    ### END CODE HERE ###

    return tokenized_sentences
```

In [11]:
```
# test your function
x = "Sky is blue.\nLeaves are green\nRoses are red."
get_tokenized_data(x)
```

Out[11]:
```
[['sky', 'is', 'blue', '.'],
 ['leaves', 'are', 'green'],
 ['roses', 'are', 'red', '.']]
```

Expected outcome

Processing math: 100%

```
[['sky', 'is', 'blue', '.'],
 ['leaves', 'are', 'green'],
 ['roses', 'are', 'red', '.']]
```

In [12]:
```
# Test your function
w3_unittest.test_get_tokenized_data(get_tokenized_data)
```

```
All tests passed
```

Split into train and test sets

Now run the cell below to split data into training and test sets.

In [13]:
```
tokenized_data = get_tokenized_data(data)
random.seed(87)
random.shuffle(tokenized_data)

train_size = int(len(tokenized_data) * 0.8)
train_data = tokenized_data[0:train_size]
test_data = tokenized_data[train_size:]
```

In [14]:
```
print("{} data are split into {} train and {} test set".format(
    len(tokenized_data), len(train_data), len(test_data)))

print("First training sample:")
print(train_data[0])

print("First test sample")
print(test_data[0])
```

```
47961 data are split into 38368 train and 9593 test set
First training sample:
['i', 'personally', 'would', 'like', 'as', 'our', 'official', 'glove', 'of',
'the', 'team', 'local', 'company', 'and', 'quality', 'production']
First test sample
['that', 'picture', 'i', 'just', 'seen', 'whoa', 'dere', '!', '!', '>', '>',
'>', '>', '>', '>', '>']
```

Expected output

```
47961 data are split into 38368 train and 9593 test set
First training sample:
['i', 'personally', 'would', 'like', 'as', 'our', 'official', 'glov
e', 'of', 'the', 'team', 'local', 'company', 'and', 'quality', 'produ
ction']
First test sample
['that', 'picture', 'i', 'just', 'seen', 'whoa', 'dere', '!', '!',
'>', '>', '>', '>', '>', '>', '>']
```

Exercise 4 - count_words

You won't use all the tokens (words) appearing in the data for training. Instead, you will use the more frequently used words.

- You will focus on the words that appear at least N times in the data.

Hints

In [15]:
```
# UNQ_C4 (UNIQUE CELL IDENTIFIER, DO NOT EDIT)
### GRADED_FUNCTION: count_words ###
def count_words(tokenized_sentences):
    """
    Count the number of word appearence in the tokenized sentences
    
    Args:
        tokenized_sentences: List of lists of strings
    
    Returns:
        dict that maps word (str) to the frequency (int)
    """
        
    word_counts = {}
    ### START CODE HERE (Replace instances of 'None' with your code) ###
    
    # Loop through each sentence
    for sentence in tokenized_sentences: # complete this line
        
        # Go through each token in the sentence
        for token in sentence: # complete this line

            # If the token is not in the dictionary yet, set the count to 1
            if token not in word_counts: # complete this line
                word_counts[token] = 1
            
            # If the token is already in the dictionary, increment the count b
            else:
                word_counts[token] += 1

    ### END CODE HERE ###
    
    return word_counts
```

In [16]:
```
# test your code
tokenized_sentences = [['sky', 'is', 'blue', '.'],
                       ['leaves', 'are', 'green', '.'],
                       ['roses', 'are', 'red', '.']]
count_words(tokenized_sentences)
```

Out[16]:
```
{'sky': 1,
 'is': 1,
 'blue': 1,
 '.': 3,
 'leaves': 1,
 'are': 2,
 'green': 1,
 'roses': 1,
 'red': 1}
```

Expected output

Note that the order may differ.

```
{'sky': 1,
 'is': 1,
 'blue': 1,
 '.': 3,
 'leaves': 1,
 'are': 2,
 'green': 1,
 'roses': 1,
 'red': 1}
```

In [17]:
```
# Test your function
w3_unittest.test_count_words(count_words)
```

```
All tests passed
```

Handling 'Out of Vocabulary' words

If your model is performing autocomplete, but encounters a word that it never saw during training, it won't have an input word to help it determine the next word to suggest. The model will not be able to predict the next word because there are no counts for the current word.

- This 'new' word is called an 'unknown word', or **out of vocabulary (OOV)** words.
- The percentage of unknown words in the test set is called the **OOV** rate.

To handle unknown words during prediction, use a special token to represent all unknown words 'unk'.

- Modify the training data so that it has some 'unknown' words to train on.
- Words to convert into "unknown" words are those that do not occur very frequently in the training set.
- Create a list of the most frequent words in the training set, called the **closed vocabulary** .
- Convert all the other words that are not part of the closed vocabulary to the token 'unk'.

Exercise 5 - get_words_with_nplus_frequency

You will now create a function that takes in a text document and a threshold `count_threshold` .

- Any word whose count is greater than or equal to the threshold `count_threshold` is kept in the closed vocabulary.
- Returns the word closed vocabulary list.

Processing math: 100%

In [18]:
```
# UNQ_C5 (UNIQUE CELL IDENTIFIER, DO NOT EDIT)
### GRADED_FUNCTION: get_words_with_nplus_frequency ###
def get_words_with_nplus_frequency(tokenized_sentences, count_threshold):
    """
    Find the words that appear N times or more

    Args:
        tokenized_sentences: List of lists of sentences
        count_threshold: minimum number of occurrences for a word to be in the

    Returns:
        List of words that appear N times or more
    """
    # Initialize an empty list to contain the words that
    # appear at least 'minimum_freq' times.
    closed_vocab = []

    # Get the word couts of the tokenized sentences
    # Use the function that you defined earlier to count the words
    word_counts = count_words(tokenized_sentences)

    ### START CODE HERE (Replace instances of 'None' with your code) ###

    # for each word and its count
    for word, cnt in word_counts.items(): # complete this line

        # check that the word's count
        # is at least as great as the minimum count
        if cnt >= count_threshold:

            # append the word to the list
            closed_vocab.append(word)
    ### END CODE HERE ###

    return closed_vocab
```

In [19]:
```
# test your code
tokenized_sentences = [['sky', 'is', 'blue', '.'],
                       ['leaves', 'are', 'green', '.'],
                       ['roses', 'are', 'red', '.']]
tmp_closed_vocab = get_words_with_nplus_frequency(tokenized_sentences, count_t
print(f"Closed vocabulary:")
print(tmp_closed_vocab)
```

```
Closed vocabulary:
['.', 'are']
```

Expected output

```
Closed vocabulary:
['.', 'are']
```

In [20]:
```
# Test your function

```

Processing math: 100%

```
All tests passed
```

Exercise 6 - replace_oov_words_by_unk

The words that appear `count_threshold` times or more are in the closed vocabulary.

- All other words are regarded as `unknown`.
- Replace words not in the closed vocabulary with the token `<unk>`.

In [21]:

```
# UNQ_C6 (UNIQUE CELL IDENTIFIER, DO NOT EDIT)
### GRADED_FUNCTION: replace_oov_words_by_unk ###
def replace_oov_words_by_unk(tokenized_sentences, vocabulary, unknown_token="<
    """
    Replace words not in the given vocabulary with the unknown token.

    Args:
        tokenized_sentences: List of lists of strings
        vocabulary: List of strings that we will use
        unknown_token: A string representing unknown (out-of-vocabulary) words

    Returns:
        List of lists of strings, with words not in the vocabulary replaced
    """

    # Use a set for faster lookup
    vocabulary = set(vocabulary)

    replaced_tokenized_sentences = []

    for sentence in tokenized_sentences:
        replaced_sentence = []
        for token in sentence:
            if token in vocabulary:
                replaced_sentence.append(token)
            else:
                replaced_sentence.append(unknown_token)  # ✅ Use the paramet
        replaced_tokenized_sentences.append(replaced_sentence)

    return replaced_tokenized_sentences
```

In [22]:

```
tokenized_sentences = [["dogs", "run"], ["cats", "sleep"]]
vocabulary = ["dogs", "sleep"]
tmp_replaced_tokenized_sentences = replace_oov_words_by_unk(tokenized_sentence
print(f"Original sentence:")
print(tokenized_sentences)
print(f"tokenized_sentences with less frequent words converted to '<unk>':")
print(tmp_replaced_tokenized_sentences)
```

```
Original sentence:
[['dogs', 'run'], ['cats', 'sleep']]
tokenized_sentences with less frequent words converted to '<unk>':
[['dogs', '<unk>'], ['<unk>', 'sleep']]
```

Processing math: 100%

Expected answer

```
Original sentence:
[['dogs', 'run'], ['cats', 'sleep']]
tokenized_sentences with less frequent words converted to '<unk>':
[['dogs', '<unk>'], ['<unk>', 'sleep']]
```

In [23]:
```
# Test your function
w3_unittest.test_replace_oov_words_by_unk(replace_oov_words_by_unk)
```

```
All tests passed
```

Exercise 7 - preprocess_data

Now we are ready to process our data by combining the functions that you just implemented.

1. Find tokens that appear at least count_threshold times in the training data.
2. Replace tokens that appear less than count_threshold times by "<unk>" both for training and test data.

In [24]:
```
# UNQ_C7 (UNIQUE CELL IDENTIFIER, DO NOT EDIT)
### GRADED_FUNCTION: preprocess_data ###
def preprocess_data(train_data, test_data, count_threshold, unknown_token="<ur
    """

Size of vocabulary: 14821
```

You are done with the preprocessing section of the assignment. Objects `train_data_processed` , `test_data_processed` , and `vocabulary` will be used in the rest of the exercises.

2 - Develop n-gram based Language Models

In this section, you will develop the n-grams language model.

- Assume the probability of the next word depends only on the previous n-gram.
- The previous n-gram is the series of the previous 'n' words.

The conditional probability for the word at position 't' in the sentence, given that the words preceding it are $w_{t-n}\cdots w_{t-2}, w_{t-1}$ is:

$$P(w_t | w_{t-n}\dots w_{t-1})$$

You can estimate this probability by counting the occurrences of these series of words in the training data.

- The probability can be estimated as a ratio, where
- The numerator is the number of times word 't' appears after words t-n through t-1 appear in the training data.
- The denominator is the number of times word t-n through t-1 appears in the training data.

$$\hat{P}(w_t | w_{t-n} \dots w_{t-1}) = \frac{C(w_{t-n}\dots w_{t-1}, w_t)}{C(w_{t-n}\dots w_{t-1})}$$

- The function $C(\cdots)$ denotes the number of occurence of the given sequence.
- $\hat{P}$ means the estimation of P.
- Notice that denominator of the equation (2) is the number of occurence of the previous n words, and the numerator is the same sequence followed by the word w_t.

Later, you will modify the equation (2) by adding k-smoothing, which avoids errors when any counts are zero.

The equation (2) tells us that to estimate probabilities based on n-grams, you need the counts of n-grams (for denominator) and (n+1)-grams (for numerator).

Exercise 8 - count_n_grams

Next, you will implement a function that computes the counts of n-grams for an arbitrary number n.

When computing the counts for n-grams, prepare the sentence beforehand by prepending $n-1$ starting markers "<s>" to indicate the beginning of the sentence.

- For example, in the tri-gram model (n=3), a sequence with two start tokens "<s>" should predict the first word of a sentence.
- So, if the sentence is "I like food", modify it to be "<s> <s> I like food".
- Also prepare the sentence for counting by appending an end token "<e>" so that the model can predict when to finish a sentence.

Technical note: In this implementation, you will store the counts as a dictionary.

- The key of each key-value pair in the dictionary is a **tuple** of n words (and not a list)
- The value in the key-value pair is the number of occurrences.
- The reason for using a tuple as a key instead of a list is because a list in Python is a mutable object (it can be changed after it is first created). A tuple is "immutable", so it cannot be altered after it is first created. This makes a tuple suitable as a data type for the key in a dictionary.
- Although for a n-gram you need to use n-1 starting markers for a sentence, you will want to prepend n starting markers in order to use them to compute the initial probability for the (n+1)-gram later in the assignment.

Hints

In [29]:
```
# UNQ_C8 (UNIQUE CELL IDENTIFIER, DO NOT EDIT)
### GRADED FUNCTION: count_n_grams ###
def count_n_grams(data, n, start_token='<s>', end_token = '<e>'):
    """
    Count all n-grams in the data

    Args:
        data: List of lists of words
        n: number of words in a sequence

    Returns:
        A dictionary that maps a tuple of n-words to its frequency
    """

    # Initialize dictionary of n-grams and their counts
    n_grams = {}

    ### START CODE HERE (Replace instances of 'None' with your code) ###

    # Go through each sentence in the data
    for sentence in data: # complete this line

        # prepend start token n times, and  append <e> one time
        sentence = [start_token] * n + sentence + [end_token]

        # convert list to tuple
        # So that the sequence of words can be used as
        # a key in the dictionary
        sentence = tuple(sentence)

        # Use 'i' to indicate the start of the n-gram
        # from index 0
        # to the last index where the end of the n-gram
        # is within the sentence.

        for i in range(len(sentence)-n+1): # complete this line

            # Get the n-gram from i to i+n
            n_gram = sentence[i:i+n]

            # check if the n-gram is in the dictionary
            if n_gram in n_grams: # complete this line

                # Increment the count for this n-gram
                n_grams[n_gram] += 1
            else:
                # Initialize this n-gram count to 1
                n_grams[n_gram] = 1

            ### END CODE HERE ###
    return n_grams
```

In [30]:
```
# test your code
# CODE REVIEW COMMENT: Outcome does not match expected outcome
sentences = [['i', 'like', 'a', 'cat'],
             ['this', 'dog', 'is', 'like', 'a', 'cat']]
print("Uni-gram:")
print(count_n_grams(sentences, 1))
print("Bi-gram:")
print(count_n_grams(sentences, 2))
```

```
Uni-gram:
{('<s>',): 2, ('i',): 1, ('like',): 2, ('a',): 2, ('cat',): 2, ('<e>',): 2,
('this',): 1, ('dog',): 1, ('is',): 1}
Bi-gram:
{('<s>', '<s>'): 2, ('<s>', 'i'): 1, ('i', 'like'): 1, ('like', 'a'): 2,
('a', 'cat'): 2, ('cat', '<e>'): 2, ('<s>', 'this'): 1, ('this', 'dog'): 1,
('dog', 'is'): 1, ('is', 'like'): 1}
```

Expected outcome:

```
Uni-gram:
{('<s>',): 2, ('i',): 1, ('like',): 2, ('a',): 2, ('cat',): 2, ('<e
>',): 2, ('this',): 1, ('dog',): 1, ('is',): 1}
Bi-gram:
{('<s>', '<s>'): 2, ('<s>', 'i'): 1, ('i', 'like'): 1, ('like', 'a'):
2, ('a', 'cat'): 2, ('cat', '<e>'): 2, ('<s>', 'this'): 1, ('this',
'dog'): 1, ('dog', 'is'): 1, ('is', 'like'): 1}
```

Take a look to the `('<s>', '<s>')` element in the bi-gram dictionary. Although for a bi-gram you will only require one starting mark, as in the element `('<s>', 'i')`, this `('<s>', '<s>')` element will be helpful when computing the probabilities using tri-grams (the corresponding count will be used as denominator).

In [31]:
```
# Test your function
w3_unittest.test_count_n_grams(count_n_grams)
```

```
All tests passed
```

Exercise 9 - estimate_probability

Next, estimate the probability of a word given the prior 'n' words using the n-gram counts.

$$\hat{P}(w_t | w_{t-n} \dots w_{t-1}) = \frac{C(w_{t-n} \dots w_{t-1}, w_t)}{C(w_{t-n} \dots w_{t-1})}$$

This formula doesn't work when a count of an n-gram is zero..

- Suppose we encounter an n-gram that did not occur in the training data.
- Then, the equation (2) cannot be evaluated (it becomes zero divided by zero).

A way to handle zero counts is to add k-smoothing.

- K-smoothing adds a positive constant k to each numerator and $k \times |V|$ in the denominator, where $|V|$ is the number of words in the vocabulary.

Processing math: 100%

$$\hat{P}(w_t | w_{t-n} \dots w_{t-1}) = \frac{C(w_{t-n} \dots w_{t-1}, w_t) + k}{C(w_{t-n} \dots w_{t-1}) + k|V|}$$

For n-grams that have a zero count, the equation (3) becomes $\frac{1}{|V|}$.

- This means that any n-gram with zero count has the same probability of $\frac{1}{|V|}$.

Define a function that computes the probability estimate (3) from n-gram counts and a constant k.

- The function takes in a dictionary 'n_gram_counts', where the key is the n-gram and the value is the count of that n-gram.
- The function also takes another dictionary n_plus1_gram_counts, which you'll use to find the count for the previous n-gram plus the current word.

Confirm that you obtain the same results as for the `estimate_probabilities` function that you implemented.

3 - Perplexity

In this section, you will generate the perplexity score to evaluate your model on the test set.

- You will also use back-off when needed.
- Perplexity is used as an evaluation metric of your language model.
- To calculate the perplexity score of the test set on an n-gram model, use:

$$PP(W) = \sqrt[N]{\prod_{t=n+1}^{N} \frac{1}{P(w_t | w_{t-n} \cdots w_{t-1})}}$$

- where N is the length of the sentence.
- n is the number of words in the n-gram (e.g. 2 for a bigram).
- In math, the numbering starts at one and not zero.

In code, array indexing starts at zero, so the code will use ranges for t according to this formula:

$$PP(W) = \sqrt[N]{\prod_{t=n}^{N-1} \frac{1}{P(w_t | w_{t-n} \cdots w_{t-1})}}$$

Exercise 10 - calculate_perplexity

Compute the perplexity score given an N-gram count matrix and a sentence.

Note: For the sake of simplicity, in the code below, `<s>` is included in perplexity score calculation.

Hints

In [60]:
```python
def calculate_perplexity(sentence, n_gram_counts, n_plus1_gram_counts,
                         vocabulary_size, k=1.0, start_token="<s>", end_token=
    """
    Calculate perplexity for a sentence using Laplace smoothing.

    Args:
        sentence: List of strings (tokens)
        n_gram_counts: Dictionary of counts of n-grams
        n_plus1_gram_counts: Dictionary of counts of (n+1)-grams
        vocabulary_size: Number of unique words in the vocabulary
        k: Smoothing constant (default = 1.0)
        start_token: Token that marks the start of a sentence (default = "<s>"
        end_token: Token that marks the end of a sentence (default = "<e>")

    Returns:
        Perplexity score (float)
    """
    if not n_gram_counts:
        raise ValueError("n_gram_counts dictionary is empty.")

    n = len(next(iter(n_gram_counts)))  # get n from the first n-gram key
    sentence = [start_token] * n + sentence + [end_token]  # pad sentence
    N = len(sentence)

    sum_log_prob = 0.0

    for t in range(n, N):
        n_gram = tuple(sentence[t - n:t])
        word = sentence[t]
        n_gram_count = n_gram_counts.get(n_gram, 0)
        n_plus1_gram = n_gram + (word,)
        n_plus1_gram_count = n_plus1_gram_counts.get(n_plus1_gram, 0)

        probability = (n_plus1_gram_count + k) / (n_gram_count + k * vocabular
        sum_log_prob += -math.log(probability)

    perplexity = math.exp(sum_log_prob / N)
    return perplexity
```

In [61]:
```
# test your code

sentences = [['i', 'like', 'a', 'cat'],
                 ['this', 'dog', 'is', 'like', 'a', 'cat']]
unique_words = list(set(sentences[0] + sentences[1]))

unigram_counts = count_n_grams(sentences, 1)
bigram_counts = count_n_grams(sentences, 2)

perplexity_train = calculate_perplexity(sentences[0],
                                         unigram_counts, bigram_counts,
                                         len(unique_words), k=1.0)
print(f"Perplexity for first train sample: {perplexity_train:.4f}")

test_sentence = ['i', 'like', 'a', 'dog']
perplexity_test = calculate_perplexity(test_sentence,
                                        unigram_counts, bigram_counts,
                                        len(unique_words), k=1.0)
print(f"Perplexity for test sample: {perplexity_test:.4f}")
```

```
Perplexity for first train sample: 2.8040
Perplexity for test sample: 3.9654
```

In [62]:
```
# Test your function
w3_unittest.test_calculate_perplexity(calculate_perplexity)
```

```
 All tests passed
```

Expected Output

```
Perplexity for first train sample: 2.8040
Perplexity for test sample: 3.9654
```

Note: If your sentence is really long, there will be underflow when multiplying many fractions.

- To handle longer sentences, modify your implementation to take the sum of the log of the probabilities.

4 - Build an Auto-complete System

In this section, you will combine the language models developed so far to implement an auto-complete system.

Exercise 11 - suggest_a_word

Compute probabilities for all possible next words and suggest the most likely one.

- This function also take an optional argument `start_with`, which specifies the first few letters of the next words.

```

Suggest multiple words using n-grams of varying length

Congratulations! You have developed all building blocks for implementing your own auto-complete systems.

Let's see this with n-grams of varying lengths (unigrams, bigrams, trigrams, 4-grams...6-grams).

In [68]:
```
n_gram_counts_list = []
for n in range(1, 6):
    print("Computing n-gram counts with n =", n, "...")
    n_model_counts = count_n_grams(train_data_processed, n)
    n_gram_counts_list.append(n_model_counts)
```

```
Computing n-gram counts with n = 1 ...
Computing n-gram counts with n = 2 ...
Computing n-gram counts with n = 3 ...
Computing n-gram counts with n = 4 ...
Computing n-gram counts with n = 5 ...
```

In [69]:
```
previous_tokens = ["i", "am", "to"]
tmp_suggest4 = get_suggestions(previous_tokens, n_gram_counts_list, vocabulary

print(f"The previous words are {previous_tokens}, the suggestions are:")
display(tmp_suggest4)
```

```
The previous words are ['i', 'am', 'to'], the suggestions are:

[('be', 0.027665685098338604),
